MANUS

MANUS *wheelchair mounted manipulator*

- Beautiful mechanical design
- Small size & light weight
- High cost (4,000,000 Yen)
- Joystick interface is not good
- Needs new communication tool

REHAB ROBOTICS

Awards

Since its invention, Handy 1 has obtained many coveted awards including:

- 1986 BBC Innovation of the Year Award
- 1986 British Computer Society Award
- 1986 International Innovation Award
- 1987 Institute of Electrical Engineers Award
- 1987 Science Times British Innovation Award
- 1987 Architecture Award for Excellence in Engineering

Handy 1 is the result of research created from the concerns of one person with disability for another. Initially designed to meet the needs of private home use, this practical device is **universally suitable for any environment** including homes, schools, hospitals or private nursing homes.

The device itself is an integration of current low power robot and microprocessor technology, housed in an ergonomically convenient package designed for ease of maintenance.

Especially formed to bring this world leading development into everyday use, Rehab Robotics Ltd. have a fundamental commitment to build a better quality of life, through robotic technology, for severely disabled people.

Future Developments
Continuous developments are planned for Handy 1, with a future programme aimed at drinking and grooming aids as retrofittable options.

Food Selection

User's guide Handy 1 to pick up food from the plate, choosing which food they want to eat, by operating the switch as the light cycle shines over their choice.

Handy 1 automatically picks up the food and presents it to the programmed mouth position.

Throughout the meal the user is in complete control of which food to eat and the pace of eating.

How does it work?

Handy 1 operates on a simple click switch selection arrangement, where personal selections are made via pairs dictated by the user.

In clinical trials this simple to operate device has proven to be an effective rehabilitation tool, opening the process of self-help.

Indicator Strip
Microprocessor controlled light sequence for user control.

Handy 1 Profile of a World Breakthrough

Why try to design an Automated Eating Aid?
Accidents and diseases cause thousands of people to depend on carers every year, leaving them with no alternative but a future of other people deciding for them what and when they eat.

Deprived of their choice of food and the pace at which they eat, they lose self confidence and often, the will to try for themselves.

Until now there has been no solution to these problems.

Attempts have been made in the past to develop a robotic unit, with little success, as they were fairly crude devices with poor control features. Limited to use with semi liquid foods at best, they could not be adapted to meet individual requirements.

The World's First Robotic Aid to Eating, Handy 1
Developed by the award winning Computer Applications to Special Education (CASE) Unit at Keele University, HANDY 1 overcomes these problems and is the first commercially available Robotic Aid to Eating in the World.

Initial User Assessment - Preparation for use

Rehabilitation professionals assess a potential user, finding a suitable eating position, then setting the most clinically effective switch's position.

Once identified, the user eating position is stored in the Handy 1 resident memory. All subsequent food presentations to this user will be consistently repeated. It has been shown that this can aid user progression towards independence.

Handy 1's Design makes food preparation an easy kitchen routine, absorbing no extra staff commitment. Everyday selections of food are arranged in us to several lines, with three 'bite sized' portions in each line.

Spoon Operation

The purpose designed spoon is mounted in a manner that allows a wide range of sitting positions. Due to its special shape, little wastage occurs in food collection and spillage is limited to a minimum during travel and lip closure. The spoon's design is contoured for eating comfort, and has been registered with the patent office.

Towards the development of other skills

Handy 1 presents the aspect of dignity in its ease of use, leading to a sense of self confidence, which in turn aids the process of self-motivation.

Benefits of using Handy 1

Being such a compact device, taking up no more space than a conventional hospital bed tray unit, Handy 1 is easily stored when not in use in home, care or work environments.

Skill Development

Because users must form their mouth correctly around the spoon, it must always be presented in a consistent manner. Robots are the only certain way in which this action can be repeatedly guaranteed, making Handy 1 the ideal solution because, whilst consistently presenting food to the user, it does not feed them.

The Result

Choice of food, pace and quantity, so returning Dignity to eating.

Some users move to independent eating through the self confidence and skill training promoted by regular use of Handy 1.

Because Handy 1 does not feed the user, positive oral motor skills are encouraged, and relaxed, positive practice is proven to help reduce unwanted reflexes.

Handy 1 is infinitely patient, reducing possible stress and tension from forced situations such as over time restraint.

With the user in control of his or her own pace and choice, the conditions are set for encouraging independence with dignity.

Blue Filter
With the practice that consistent presentation brings, this rather disappears in many cases.

Eye hand co-ordination
The repetitive selection routine followed enables the user in development of co-ordinated movement.

Lip Flexion
The purpose designed spoon prompts lip closure improvements by consistent presentation of food to the user.

General
The Handy 1 control switch flexibility is invaluable when physical movements are limited. Most eating positions can be catered for due to the integrated design of the robotic arm and frame.

The actual Care Robotics System

- One task robot was developed in practical use.
- Interface between human and robot is important.
- Hand and image processing is important factor.
- How to reduce the cost, mass production ?
